RELIABLE PROCESSES

Strategies from experience
Editorial

Dear Reader,

Don’t be surprised if you think you’re seeing double while reading this edition of Klartext. That’s because it contains a number of “twins;” however much they may differ from each other in significant details.

The companies WB mechanics and Endutec, for example, are both headquartered in Upper Bavaria and have been using StateMonitor to optimize their processes with great success. In this regard, they are similar, but what they actually do is quite different.

Our report about Endutec also contains certain parallels to our story about the Keck Observatory in Hawaii. Both involve outer space: the Endutec story is “just” about the moon, while the Keck Observatory report is concerned with infinite expanses.

The companies Doppelmayr (Italy) and Sermec (Portugal) are our southern European “twins.” Both companies machine large parts and employ full-surface machining with the TNC 640 to reliably attain their manufacturing goals. But whereas milling-turning is the Italian company’s combination of choice, the Portuguese firm is a big fan of milling and hobbing on a single machine.

By the way, this edition of Klartext even includes a digital twin. With this new offering from the HEIDENHAIN Service department, a nearly perfect virtual copy of the machine comes straight from the shop floor to your design office.

And, of course, this edition of Klartext also contains some one-of-a-kind stories:
- Nicholas Hacko, the highly successful watchmaker in Australia
- The TNC Specialist program, for helping TNC Club premium members stem the skills shortage
- The collection of online expertise available in the Klartext Portal
- The EMO 2019 trade show in Hannover, where HEIDENHAIN will be showcasing exiting innovations

So take a close look, and discover new ways to keep on improving! Happy reading!

EMO 2019: discover process reliability and innovations

+ In this edition of Klartext, starting on Page 12
+ In Hannover at three booths in Hall 9
+ Already online: emo.heidenhain.de
WB mechanics in Putzbrunn near Munich, Germany, relies on state-of-the-art machines and StateMonitor for process optimization.

Consistently better

Rossmair sums up the philosophy behind his business success in simple terms: "We concentrate wholeheartedly on our strengths. What we do, we want to do correctly, efficiently, and to the highest level of technology." That's why the tidy production shop at WB mechanics is equipped entirely with milling machines and lathes. "We deliberately forgo other processes such as electrical discharge machining or grinding."
The production floor at WB mechanics: six milling machines with HEIDENHAIN controls, along with six lathes, are all connected to StateMonitor.

Always at the forefront of technology

"As a precision machining service provider, we primarily produce single parts and small series. Runs of 1000 parts are a real exception," says Rossmair, describing his business. These jobs mainly include prototypes and pre-production samples with stringent quality and accuracy requirements. WB mechanics is able to meet these requirements thanks to its qualified personnel and continually state-of-the-art machines. "All of our workers are specialists for 5-axis milling machines and EMCO turning centers, and none of our machines are more than five years old. This allows us to take the next technological step forward every time a machine is replaced," explains the successful business owner with a touch of pride.

For Rossmair, the efficiency of his processes is at the forefront of his business decisions and investments. At the moment, he is primarily focused on two strategies. "In view of our relentless focus on 5-axis machining for milling, I’d now like to implement full-surface machining on all machines, including for turning," he says, explaining his investment in a new EMCO HYPERTURN 65. "I’d also like to consistently minimize time lost during production."

StateMonitor for all machines

WB mechanics has been deploying StateMonitor for precisely this purpose since the beginning of 2019. In search of a solution for monitoring his machine tools, Rossmair came across the StateMonitor Internet sites. "It was exactly the solution I was looking for because it promised to connect machines regardless of their manufacturer." Since WB mechanics was already very familiar with HEIDENHAIN as a control manufacturer, Rossmair didn’t hesitate for long. "When I purchased a new Alzmetall GS machine, I ordered StateMonitor along with it."

"We’re always open to new technologies. We look at them and then pick out the things that’ll take us a step forward—like StateMonitor."

Bernd Rossmair
After just over six months, his assessment is positive: “Connecting the milling machines with HEIDENHAIN controls was no problem at all. The EMCO machines were connected via OPC UA. However, a few things had to be adapted due to the different server versions on the various machines, for example. But HEIDENHAIN and EMCO quickly resolved those matters.” Rossmair is enthusiastic about the support. “Our queries and requests were always taken seriously and dealt with quickly.” For example, he was initially dissatisfied with the depth of data that StateMonitor could retrieve over the OPC UA interface. “But I think I was kicking at open doors with my request. The response and necessary modifications came immediately,” he says.

How does WB mechanics benefit from StateMonitor in its daily routine?

The employees are happy about having a lot less legwork. Now they can use StateMonitor to keep an eye on their running machines while they’re in the office editing programs for the next jobs or setting up another machine tool. “We did write programs in the office before StateMonitor, but the staff had to run out to the machine every 30 minutes or every hour to see if things were still running. Most of the time it went well, but sometimes the machine stood idle for quite a while, and valuable time was lost,” notes Bernd Rossmair about the difference to now. “They can now monitor everything from the office and work on their programs in peace. This prevents unnoticed downtime and also helps them concentrate.”

The staff also has complete access to all information and processes. Not all of the credit goes to StateMonitor, though: for complete networking of the shop floor with the production planning department, WB mechanics also uses Remote Desktop Manager on its HEIDENHAIN controls. “We have a basic membership in the TNC Club and chose Remote Desktop Manager as our free sign-up software option. This enables us to access the CAM system directly from the controls and update data from the shop,” says Rossmair, visibly pleased with his efficiently digitalized operation.
WB mechanics also uses StateMonitor on its shopfloor machine controls. For Markus Hollerieth, the software makes it easier to operate multiple machines.

Looking ahead to the next steps

What is the enterprising business owner planning next? “The Batch Process Manager software for HEIDENHAIN controls is intriguing, and I’d like to take a closer look at it,” says Rossmair. “I’m also considering a premium membership in the TNC Club. The on-site user day is certainly appealing as well. While StateMonitor was being installed, I kept noticing how much we benefited from having experts come into the company bringing new perspectives and ideas.”

How StateMonitor takes you forward:
www.heidenhain.com/statemonitor

A service provider for precision machining:
www.wbmechanics.de
How many parts manufacturers can claim that their workpieces will fly to the moon? Endutec, a twelve-man operation based near Lake Chiemsee in Germany, decided to reach for the stars: they milled 30 parts that were initially said to be unmillable. These components are now an integral part of the "Mission to the Moon," the first German lunar mission.

It’s the year 2104. The spaceship Covenant is on its trajectory to a distant planet. Upon landing, the crew believes itself to have arrived on a habitable paradise. Maggie Faris sets out to explore unknown territory with the Audi lunar quattro. However, the crew soon realizes that it is trapped on a sinister world.

While most science fiction vehicles originate from the creative pen of Hollywood, the movie "Alien: Covenant" is an exception. The Audi lunar quattro moon rover is very much a reality and is set to play a key role in an actual mission to the moon. Half a century has passed since Neil Armstrong walked on the moon. Now, the German new-space startup PTScientists from Berlin aims to return to the Apollo 17 landing site in the Taurus-Littrow valley. Together with its partners, the company has developed the ALINA lunar lander and the Audi lunar quattro moon rover.

"It quickly became clear to us that this was a unique opportunity, and we simply had to say yes," says Andreas Flieher, managing director of Endutec. He set about implementing the project together with his partner Michael Hascher and a team of design engineers and milling machine operators. They faced three major challenges.

The mission
For manufacturing the moon rover components, the team of developers initially approached established manufacturers in the aerospace industry, who declared the parts to be unproducible. It wasn’t until talking with Endutec near Lake Chiemsee that PTScientists found willing ears. The custom machine manufacturer normally produces high-precision manipulators for the semiconductor industry and has built up a further mainstay with its own automation concept.

The obstacles
The concerns expressed by the aerospace companies proved to be true: the design had to be modified to make the components millable at all. "All of the walls are very thin, because in the aerospace sector every gram counts," explains Flieher. One need only consider the current lunar freight costs, which start at 800,000 euros per kilogram.

Secondly, the deadline of just under two months was extremely tight. This is nothing new in the lunar mission busi-
Preparing new jobs and monitoring them is no problem with StateMonitor.

Andreas Flieher and Michael Hascher with parts of the moon rover.

ness; NASA also faced enormous deadline pressure after John F. Kennedy announced his intention to put a man on the moon by the end of the 1960s.

Thirdly, the extremely long production times of up to 14 hours had to be implemented with existing capacities and despite full order books. “The only way was to exploit nights and weekends using our own automation technology,” says Flieher. “This included our assembly robot in combination with StateMonitor from HEIDENHAIN, which actively informs us about the statuses of our machines.”
To achieve anything, you have to know exactly what you want, think the steps through, and then finally get going.

Andreas Flieher, Endutec

The strategy

Endutec set a clear goal for itself and scheduled the lunar project accordingly. “To achieve anything, you have to know exactly what you want, think the steps through, and then finally get going. The danger is turning back halfway when difficulties arise,” says Flieher. But turning back is out of the question for this managing director. He’s too ambitious for that. “As a business owner, you strive to make the best of any situation. I like to tackle challenges and achieve something.”

Implementation phase

By the time the lunar vehicle parts entered production, the team at Endutec had a clear plan. During the day, the staff worked on orders from existing customers. As evening approached, they clamped the blanks for the moon rover parts into the automation system, particularly those parts requiring long run times. The robot would then load the parts at night and on the weekend.

“Of course, unattended operation doesn’t always go smoothly,” says Flieher. “I remember a situation when the machine reached its coolant minimum on the weekend. Without State-Monitor’s push notification, we would have lost two production days.” The active notification provided by the MDA software significantly eases the workload. Flieher explains: “In the past, we used to have a webcam installed in the machine. So, to check the machine status, I had to actively dial in. This meant I was constantly under stress in the evenings and on weekends.”
The automation technology

From the very beginning of Endutec, Flieher and Hascher gave a lot of thought to the automation and digitalization of processes. They started out as an engineering firm in 2009 after the company they had previously worked for shut its doors during the financial crisis. Three years later, they set up their own production plant, including their own recipe for automation, which they now sell to other companies.

“We use a combination of technologies; that is, automated machine loading with our robot system and the monitoring capability provided by StateMonitor. That makes us efficient,” says Flieher, who is convinced of the positive effects that automation has on the work of his employees. They can do their jobs in a much more relaxed manner because they can concentrate on more qualitative tasks or even sometimes leave work earlier.

The potential

Endutec has discovered how to take advantage of the digital revolution. This is because the best way to get a return after investing in machines is by fully utilizing available capacities. “In this area as well, we used StateMonitor to identify hidden potential and increase machine utilization,” says Flieher. It’s how a twelve-man company manages to achieve something extraordinary alongside their everyday tasks. “This project really motivated every one of our employees. After all, how many people can claim to have made workpieces that will fly to the moon?”

Unattended shifts were the only way to meet the tight deadlines.
Discover process reliability

Reliable mastery of all production-related processes creates a clear competitive advantage. At the EMO trade show, HEIDENHAIN will be showcasing new solutions for this mastery.

Would you like to mill and turn with high process reliability, accuracy, and productivity even with lot size 1? And would you like your production machines to be fully digitally integrated into your process chain? Then a visit to HEIDENHAIN at EMO will be well worth your while. At EMO, we’ll be presenting not only the TNC 640 with a 24-inch widescreen and Extended Workspace Compact, but also, in Hall 9, there will be three stations where you can discover new HEIDENHAIN ideas for your production processes and observe them in action. Here’s what awaits you in Hannover:
OCM: the next generation in trochoidal milling

You’re already familiar with trochoidal milling from the Dynamic Efficiency package of functions for the TNC controls. The new Optimized Contour Milling (OCM) function will give you an expanded option, allowing you to program trochoidal milling operations for any pocket and island directly on the control in the shop. All you have to do is enter the contours. The control then automatically calculates the best trochoidal strategy. This allows you to harness highly efficient trochoidal milling processes for a much wider range of workpieces, thereby increasing productivity and reducing tool wear. Come watch a live demonstration of OCM at our main booth.

Milling, turning, and grinding in a single setup

How would it be if, in addition to milling and turning, you could soon use your machining center with a TNC 640 to also jig grind, and all of this in a single setup? A live demonstration will introduce you to the new grinding option. This option allows you to jig grind any contour, and it is programmed in a manner similar to the already existing machining operations. Optimized tool management supports you with every single process, including dressing, so that you can give your parts a perfect surface finish.

Monitoring spindles and feed axes

The new Component Monitoring feature of the TNC controls keeps a close eye on machines in order to protect them from malfunctions arising from overloading and wear. The continuous monitoring of the spindle bearing load prevents defined limit values from being exceeded, thus hindering damage to the spindle. Cyclic monitoring of the feed axes provides insight into ball-screw wear and anticipates pending failure. The Component Monitoring feature of the TNC increases process reliability, productivity, and machine service life while also reducing unplanned machine downtime and its consequent high costs.
Intelligent data management through digital networking

Digital networking and the opportunities it provides for machine data acquisition, equipment monitoring, and process monitoring require universal, standardized interfaces. Monitoring solutions, such as the StateMonitor software, reach their full potential and are simple to connect only when standardized information can be exchanged between participants across systems.

HEIDENHAIN will be demonstrating this kind of networking at the EMO trade show. Machines with very different controls at the booths of various machine manufacturers will be connected to the HEIDENHAIN booth via the MDA software StateMonitor. In connection with this, HEIDENHAIN is also supporting “umati,” an interface project from the German Machine Tool Builders’ Association (VDW).

In addition, live demonstrations of StateMonitor can be watched at the “industrie 4.0 area.” There, HEIDENHAIN, OPS-Ingersoll, and Haimer will be showing just how much process reliability a digitally networked production environment can offer. Special focus will be placed on the exchange of tool data: during the live demonstration, a data chip on the tool holder will be used for the first time to scan the tool magazine before writing the tool data to the tool table. This will be done without paper or any intervention by the operator.

The TNC Club’s answer to the skills shortage: the TNC Specialist program

As a meeting place for expert know-how for all TNC users, the TNC Club will once again be on-site at EMO with its own booth. Here, focus will be placed on the advanced training of experienced specialists as well as on the apprentice-level training of qualified junior employees. Along these lines, the TNC Club will be presenting a new training program for career jumpers: the TNC Specialist program. With this program, HEIDENHAIN would like to support TNC Club premium members in combating the skills shortage.
Control technology that moves intelligently

At EMO, HEIDENHAIN will also be unveiling its new Gen 3 drives for the first time. This generation of drives is a perfectly harmonized, self-contained system based on particularly innovative and future-oriented technologies. You benefit from high surface quality and short production times thanks to:

- Improved performance data for optimum results
- The newest interfaces for intelligent transmission technology
- Powerful diagnostics for high availability
- Simple mounting and connection technology

How important is measurement technology for process reliability?

In addition to the new features of its controls, HEIDENHAIN will once again be focusing on the importance of measurement technology for process reliability. Even though linear and angle encoders do their work behind the scenes, the choice of the right encoder is a decisive factor in attaining reliable processes and highly accurate production results. A demonstration unit equipped with various angle encoders on a torque motor from ETEL will illustrate the influence of the measuring principle on the dynamic performance and accuracy of rotary axes. At the same time, it will reveal the system architecture for digital temperature monitoring of the motor.

About the meeting point for expert know-how:
www.tnc-club.de

The “industrie 4.0 area” online:
mav.industrie.de/industrie-4-0-area-2019
Doppelmayr Italia actually needed a large lathe. Instead, it bought a 5-axis milling machine that can also turn.

“Wow” is the first thought that comes to a visitor’s mind when he stands in front of the new FPT Dinomax at Doppelmayr Italia in Lana, South Tyrol. The machine’s production repertoire includes cable sheaves for cable car systems, which nowadays carry passengers not only up high mountains but also between airport terminals, for example. To manufacture such products, the South Tyrolean company employs innovative technology on a massive scale. Thanks to a TNC 640 on the FPT Dinomax, the company can mill and turn workpieces up to 4.2 meters in diameter and weighing up to 15 metric tons—all in a single setup. Even a Klar text editor doesn’t see a machine of this size every day.

It was clear to everyone involved at Doppelmayr that the company’s old facing lathe needed to be replaced. But what machine would fit the bill? Lorenzo Benvenuti, head of production and procurement at Doppelmayr Italia, describes the situation at the time: “In years past, large cable sheaves were made entirely by our parent company in Austria. But now, we in Lana were expected to relaunch production whenever single parts and special solutions were needed. We weren’t anticipating the high quantities that would fully utilize a dedicated lathe.”

Choosing a control: (not) a hard decision

Against this backdrop, the machine manufacturer FPT provided the decisive tip: a Dinomax milling machine with a rotary table for vertical turning. Between turning jobs, the machine could still be fully utilized for milling work. But which control should the machine have? A lathe control that can also mill? Or a milling control that can also turn? “Milling is by far the more complex process, and we wanted to have reliable mastery over it. So we went with the HEIDENHAIN TNC 640. When it comes to milling, HEIDENHAIN is our go-to product,” explains Lorenzo Benvenuti.
The machine has been in operation for about a year now. “You can have a plan for everything, but the world always ends up turning in the opposite direction,” laughs Lorenzo Benvenuti, recalling the 20 large cable sheaves that have already been run on the machine this year alone. Among them were the heaviest sheaves that Doppelmayr Italia has ever made. Prior to machining, the workpiece blanks of these huge, yellow-painted wheels, each featuring two cable guides, weighed roughly eight metric tons. Now they are waiting to be shipped to London Luton Airport, where they will soon be shuttling airport guests from terminal to terminal in speed, comfort, and safety.

Accuracy is key

Comfort and safety are key requirements in this kind of cable car project, and accuracy is a decisive factor in attaining them. For their 3.6-meter outer diameters, the giant cable sheaves for London Luton Airport must meet tolerances down to a tenth of a millimeter. Tolerances for the bearing seats and brake surfaces are even as low as the famed hundredth of a millimeter. Such accuracies ensure the long service life, reliable functioning, and jerk- and vibration-free operation that make for a pleasant ride.
Due to the machine’s unexpectedly high utilization rate, absolutely everything on it must work as intended. Franz Frei, head of production and therefore the machine’s “boss,” is satisfied on the whole. “Of course, there were some teething problems in machining the large cable sheaves. At these dimensions, turning becomes a complex process with its own unique set of pitfalls,” notes Frei. When you stand next to the machine and feel the forces at work while a roughly two-meter wide sheave is being machined (what Frei calls “a small sheave”), you can just imagine what the machine has to withstand when working on an eight-ton specimen.

The machine assists with many tasks

“And when everything is new—the machine, control, and CAD/CAM program—something will inevitably go wrong somewhere,” remarks Frei, who holds a very pragmatic view of the initial phase. But now everything works well. The machine manufacturer FPT, the CAD/CAM supplier HyperMill, and HEIDENHAIN were always on-site when adjustments were needed. Some turning cycles still had to be optimized, for example, and programming improvements were made for turning processes in the CAD/CAM system. “The machine provides optimal support and relieves us of many tasks,” Frei is now pleased to report. For example, the machine is equipped with three heads for the various machining operations:

- A spindle extension for machining workpieces with deep, narrow pockets and other elements
- A universal head with a mechanical gear system and freely selectable angles for inclined machining
- A head for heavy turning

The head for heavy turning can be indexed automatically. This facilitates the use of short tools that enable faster machining and higher accuracy. “If the NC program requires a change of heads, then the machine automatically switches to the correct mode,” says Frei. “During milling, the table is then either stationary or freely rotatable, whereas during turning, it can spin at up to 180 rpm.”

“With programs from the CAD/CAM system, milling and turning are no problem at all: for milling, we program smaller jobs and modifications directly on the machine’s control,” confirms TNC user Christof Karlegger, one of the two tradesmen who operates the Dinomax. His previous role at Doppelmayr Italia involved working with a HEIDENHAIN iTNC 530 on one of the company’s travelling column milling machines. “For turning, I personally work entirely with CAM data from the design department,” he says. “I’m not yet that familiar with how to write turning programs on the control.” A special training course from a HEIDENHAIN end-user consultant will soon remedy that.

Process reliability from the get-go

For the creation of its NC programs, Doppelmayr Italia relies entirely on the expertise of its skilled tradesmen at the machine. “Only those workers who know and master the machine are qualified to program in the CAD/CAM system,” insists Frei. “If there’s a mistake in the CAD/CAM program, then that sends us all the way back to square one. It’s definitely better to know, for example, what needs to be considered with regard to workholding.” That’s why every program is first simulated in HyperMill before going to the machine.
“With the 3-D simulation function of the TNC 640, I can immediately determine whether a machining operation will really work.”

Christof Karlegger, TNC user

The TNC user then takes another look at particularly critical sub-processes in the 3-D graphical simulation of the TNC 640. “In the normal view, I often can’t discern the sheave contours or the tool with adequate precision,” says Christof Karlegger. “I can’t really see the exact infeed point of the tool, for example. But in the 3-D simulation, I can verify all of that very carefully and ensure that the machining operation really will run without a glitch.” For Doppelmayr Italia, this long-range verification of cycles is a very important criterion for process reliability. Nobody here can or wants to risk several tons of scrap and potentially many hours of lost time.

The “small” two-meter sheaves look almost tiny inside the machine room of the FPT Dinomax.
"Shortage of skilled labor brakes growth," "Too much work, too few workers," "Skilled labor is missing everywhere": the shortage of well-trained workers in Germany is frequently in the headlines. A study by the economic research institute Prognos shows that Germany will face a shortage of 2.9 million specialists by the year 2025. And for craftsmen, technical trades, and STEM professions, the problem is chronic. However, answers to this deficiency are gradually cropping up in places.

HEIDENHAIN, for example, has now launched its TNC Specialist program. In a multi-stage training program that includes practical hours at one’s company, the participants are introduced step by step to complex programming and operating content. What sets the TNC Specialist program apart is its use of a modular curriculum to take different levels of prior knowledge into account. Regardless of whether the participants are career jumpers without any prior knowledge or experienced metalworkers, program participants are able to quickly acquire a solid working knowledge of the TNC control.

This training program is a quick and cost-effective way to obtain high-quality certification. A closely woven support system, flexible times, and generous training discounts combine to create the optimal conditions for feasible and company-friendly occupational development. After successfully passing the final exam, participants receive the “TNC Specialist” certificate from HEIDENHAIN. This marks them out as TNC specialists and confirms that they possess the expertise needed to independently perform complex operating tasks.

Pre-qualification
Each participant enters the program at the appropriate level based on his personal level of training. For career jumpers from other fields, the program begins with a course on the fundamentals of metalworking. This entry-level course lasts two weeks and, based on practical examples, covers the manufacturing processes used within the field of metalworking. Participants who have already demonstrated metalworking knowledge can skip this pre-qualification course.

Training in fundamentals
Then the TNC Specialist training begins. This stage starts off with a self-learning course based on the current HIT learning software from HEIDENHAIN. The TNC Specialist program includes a virtual classroom. Throughout the training period, this classroom serves as a learning aid and a communication platform for the HEIDENHAIN trainers and course participants. The classroom contains forums where open topics can be discussed and where schedules and syllabuses are posted.

Following this comes a basic course covering the fundamentals of TNC programming. After this course, the participants will already be able to perform simple operating and programming tasks on their own. Participants solidify their newly acquired knowledge back at their company through practical work at the machine.
Here is an overview of the topics covered by the TNC Specialist program:

- Creation of simple and complex Klartext conversational programs
- File management and file transfer
- Setup of workpieces
- Preset management
- Machining of workpieces
- Error analysis and troubleshooting
- Correcting programs and restarting mid-program
- Measurement of workpieces with automatic probing cycles and documentation of the results
- Entering, editing, and managing tools
- Measurement and compensation of tools

As part of the TNC Specialist program, premium members have the option of benefiting from an annual “user visit.” This one-day visit by a user consultant in a production setting—ideally right after completion of the basic course—helps participants apply their acquired knowledge directly at their workstation. Additional visits can be booked on an individual basis.

**In-depth training**

The advanced course introduces participants to more complex programming techniques, such as automatic probing cycles, fundamentals of tilted machining, Q-parameter programming, and FK programming. The content covered in the advanced course is also solidified through further practical hours back at the company.

In the span of two days, the optional supplemental course entitled “Tool technology” imparts practical and theoretical knowledge about the efficient use of different tool types. Other topics include the calculation of cutting data, the effects of tooling on surface quality, and scrap avoidance. This course is offered by an official tool partner of HEIDENHAIN.

**Final examination**

After completing all of the required modules, participants come to the HEIDENHAIN training center in Traunreut to take the final exam. The exam contains a theory section covering basic topics, questions about control functions, and operating rules for TNC programming. In the practical section, the examinee uses a programming station to program a workpiece designed to test his proficiency in all of the topics from the basic and advanced courses. Without help, the participants must then import the finished program to a machine in the training center. There, they are required to chuck the workpiece blank in the machine and answer various questions. The workpiece is then milled and evaluated. Participants who pass all sections of the exam are given certificates confirming them as TNC specialists.

  The HEIDENHAIN forum is a great place for users to get fast help from other end users. After all, among our 6200 followers, there is bound to be a TNC expert who can help with your questions.
The HEIDENHAIN training program covers the entire gamut of control-related knowledge. After all, we want to help you get the most out of your control, whatever your application may be.

Self-learning with HIT

Less is more? Certainly not when it comes to knowledge and expertise! That’s why we created HIT 3.0, a multimedia learning platform for NC programming, so that you can teach yourself new skills as an NC user, including on mobile devices. We also have very attractive offerings for teachers and trainers.

Webinars

Thoroughly and clearly explained: trainers from the HEIDENHAIN training center explain various functions of the TNC and CNC PILOT controls in 60 minutes.

What else is in our media library?

- Klartext reports with extra information about the articles in the printed magazine
- Product videos about our controls and their functions
- User’s manuals for current and older control models
- Brochures about our controls

HEIDENHAIN helplines

With our free helplines, you receive immediate and direct support from specialists in various fields.
The rotary table enables the horizontal machining of parts weighing up to five metric tons.
USER REPORT

Big and accurate

Sermec Group, based in Portugal, machines large parts in a single setup using HEIDENHAIN controls on machines from Soraluce.

Sermec Group counts wind turbine builders, steel mills, cement factories, and refineries among its customers. The company from Folgosa near Porto supplies them with high-precision parts, usually in low quantities or even in lot size 1. That’s why the company selects machines with the perfect combination of flexibility, productivity, and accuracy. With its FS 10000 traveling-column milling-turning center from Soraluce and a HEIDENHAIN TNC 640, Sermec can manufacture gears and axes for wind turbines with full-surface machining—including difficult gear teeth.

Sermec wanted to perform milling, boring, turning, and hobbing operations in a single setup on a single machine featuring enough room to accommodate various types of large parts. This would significantly boost the company’s productivity and manufacturing accuracy, giving it a clear edge in the competition for production jobs and in meeting the rigorous standards of high-tech customers. So, Carlos Pereira, technical director at Sermec, started looking for a solution to meet this remarkable requirements profile. His search came to an end at Soraluce.
The Soraluce FS 10000 features a special milling head for the hobbing of large gear teeth.

High productivity through multitasking

With traversing paths of 10,000 mm x 3600 mm x 1600 mm across a worktable that is 11,000 mm long and 2500 mm wide, the Soraluce machine provides Sermec with sufficient room for the workpieces it typically produces. Added to the mix is a rotary table with a diameter of 2000 mm that is well-suited for both vertical and horizontal machining. The machining center therefore allows 4-axis machining and is optimally equipped for all production jobs. A variety of milling heads—a steplessly tiltable universal milling head, a fixed horizontal milling head, and a boring and face-turning head—along with a tool change system featuring 60 pockets, ensure that the best tool for the upcoming machining operation is always inserted in the machine.

Control of the myriad possible operations is performed by a TNC 640. “Hobbing capability is particularly important to us,” explains Pereira. “It opens up completely new opportunities in the large-part machining market.” Intuitive operation of the cycles makes the production of, say, large gear parts and axes for wind turbines not only easy but also productive and therefore lucrative. This is particularly true because Soraluce has developed a milling head specifically for hobs. “The hobbing cycle from HEIDENHAIN synchronizes the movements of the rotary and linear machine axes with perfect choreography for the hobs,” says Pereira, describing the shop’s new production abilities.

The control isn’t the only thing from HEIDENHAIN

Soraluce doesn’t rely on HEIDENHAIN just for its controls; inside the FS 10000, other HEIDENHAIN solutions are also busy at work behind the scenes. Its motors and encoders come from the HEIDENHAIN production facilities in Traunreut: servomotors, linear encoders, and angle encoders provide accuracy and dynamic performance for the positioning of the machine table, rotary table, and spindle drive system. And, just like the TNC 640, these components share the typical characteristics of Soraluce machines: high accuracy, great dynamic performance, high stability during machining, and maximum availability.

“A key advantage is the simple, truly intuitive operation of the HEIDENHAIN cycles.”

Carlos Pereira
NH Watches has been designing and producing its own watches since 2016: they really are “made in Australia.”

Exclusive watches “made in Australia”? Nicholas Hacko makes it possible. The watchmaker runs a small but remarkable production facility in Sydney. In order to be flexible and competitive, the entrepreneur invested in a 5-axis machining center with which he reliably produces tiny parts to micron-level accuracy.

Originally from Europe, the Hacko family has a long tradition of watchmaking. When Nicholas Hacko emigrated to Australia in 1992, he was his family’s third generation of watchmakers. He initially limited himself to repairing all types of timepieces, just like his ancestors. But he wanted more: “I knew early on that I wanted to use my creativity and make my own watches.” In 2011, he took his first step toward this goal when he founded “Nicholas Hacko Watchmaker,” often simply referred to as NH Watches. Five years later, he created his first entirely self-designed and developed watch.

Producing tiny parts to micron-level accuracy

Along with creativity and entrepreneurial spirit, two additional factors are crucial to the success of NH Watches: on the one hand, the company’s seven employees, and on the other, the KERN Pyramid Nano high-precision 5-axis machining center with an iTNC 530 control from HEIDENHAIN. It never ceases to thrill Nicholas Hacko: “This machine mills very small gears, bridges, pallets, mainplates, and other micro parts to greater accuracy than is actually required.” To put this into numbers, Nicholas Hacko typically requires a production accuracy of between 6 µm and 10 µm in order to ensure that his watches keep perfect time for a lifetime. In exceptional cases, some mainplates even require hole separations of just ±2 µm. The Pyramid Nano reliably attains a machining accuracy of better than 1 µm throughout its service life.

A used machine with flawless precision

These extraordinary characteristics are the reason why the Australian watchmaker long had his eye on a machine from KERN. At the AMB trade show in 2016, he saw one in action for the first time, which only confirmed his opinion: “I was convinced that a machining center of this type would be ideal for my needs.” When the possibility of purchasing a used machine came around, Hacko quickly made up his mind to buy it. According to KERN, the machine’s performance and machining accuracy remain unchanged throughout its service life. “That’s just like with my watches,” says Hacko. After a year of experience with his 5-axis milling center, Hacko is also very satisfied with its ease of operation. The easy-to-understand programming language, the straightforward operating design, and the many possibilities offered by the control leave nothing to be desired. As Hacko says, “The machine produces each part exactly as we programmed it. It simply doesn’t make mistakes.”
Thanks to an iTNC 530 control from HEIDENHAIN and the Klartext programming language, NH Watches can manufacture its parts to even greater accuracy than is actually required.

Highly precise micro parts like this mainplate ensure that timepieces from NH Watches keep time correctly for the duration of their service life.

“...The machine produces each part exactly as we programmed it. It simply doesn’t make mistakes.”

Nicholas Hacko

Contract manufacturing as an additional source of income

Recently, NH Watches has started using its Pyramid Nano not only for its own watch production but also to manufacture micro-precision parts on a contract basis for the medical technology and mold-making industries. With no significant competition for this type of service in Australia, Nicholas Hacko is confident about the future: “It’s a great feeling to be the only business owner in Australia with a high-precision machining center of this type. I’m sure this will give us a lot of growth potential, and I’m looking forward to being able to buy more KERN machines in the future.”

The original on the shop floor: a 5-axis machining center with a TNC 640.

With the digital twin, the programming station in the design office has a nearly perfect copy of the machine on the shop floor.

A programming station from HEIDENHAIN is an exact copy of a control. But it's a copy purely of the control: it doesn't duplicate the machine itself. The HEIDENHAIN Service department is now changing this state of affairs with its offering of a digital twin.

Hans-Peter Wimmer normally works as a CAM programmer for HEIDENHAIN encoder prototypes. But in recent weeks, he has also been involved in the development of a new offering from the HEIDENHAIN Service department: he has been a beta tester of the new digital twin. "As it is, the programming station is pretty nifty," Hans-Peter Wimmer says while describing the project. "After all, it's an exact copy of the control. But until now, it could provide only a simplified model of the machine."

This meant that programs coming from the design office—especially very difficult machining operations—always had to be simulated directly on the machine, just to be sure (e.g., with a simulation run). "That always cost us lots of valuable time at the machine," says Wimmer, highlighting the main disadvantage. Or one had to invest in an equally expensive virtual machine. "With the digital twin on the programming station, I now have a true copy of the machine kinematics in my office, allowing me to run verification simulations directly on the machine."
tests as if I were on the shop floor," he says. "That gives me much greater confidence that the program will run correctly when I’m at the machine." This reduces setup and simulation time as well as re-programming work on the shop floor. It also improves process reliability, thereby increasing overall productivity.

"The digital twin brings the machine right into my office, allowing me to account for its particular configuration during CAM programming and start production sooner."

Hans-Peter Wimmer

After a thorough upgrade, the Keck Observatory telescopes in Hawaii can now see with even greater precision.

In many observatories around the world, HEIDENHAIN measurement technology ensures the accurate pointing of telescopes into the night sky. The Keck Observatory in Hawaii is no exception. Over the course of roughly thirty years, astronomers and astrophysicists have made a number of sensational discoveries here. Now, after renovation of the drive system and measurement technology, these telescopes can view the heavens with even greater resolution and accuracy.

Atop Mauna Kea, roughly 4200 meters above sea level, the 30-meter high domes of the twin Keck telescopes tower into the clear, dry air over Hawaii. Their 10-meter wide mirrors permit exceptional views of the night sky and are able to collect light from both the visible and infrared spectrums. For enhanced performance, they can also be used in concert to act as one massive, adaptive optical system.
Nine years of renovations under challenging conditions

What these massive optical systems are ultimately able to see depends to a large extent on how accurately their mirrors can be pointed at the night sky. The greater the positioning accuracy, the more accurately astronomers are able to target, track, and observe a given region of the universe. This applies both to the azimuth, the horizontal orientation along the points of the compass, and to elevation, the vertical orientation relative to the zenith. For these reasons, the entire drive system technology of the telescopes was renewed and optimized.

Astronomy deals with notions of space and time very different from those of everyday life, and this was also evident in the renovations made to the Keck telescopes. Taking nine years to complete, the project was planned and executed under extraordinary conditions:

- During the renovation period, the astronomers at the Keck Observatory were supposed to enjoy full use of both telescopes. The renovation work, which was carried out during daylight hours, had to be planned such that the telescopes were ready for use again by nightfall.

- The telescopes are located 4200 meters above sea level. Due to the lower air pressure and oxygen levels at this altitude, people ascending to the telescopes require breaks in order to acclimatize. In order to work properly, technical systems must also be adapted to the surrounding conditions.
The new measurement technology allows the telescopes to be pointed at a star with greater speed and accuracy, as well as track its movement over an extended period.

“Now, considerably more accurate data, and much more of it, can be made available to astronomers and astrophysicists around the globe.”

Tomas Krasuski, lead electronics engineer
For nearly absolute position measurement, the new angle encoders in the Keck telescopes feature markings on a separate scanning track in addition to the incremental track.

Mounting configuration of the ERA 8400 angle encoders on the telescope drive system for azimuth positioning.

The ERA 8400 angle encoders on the drive system for elevation positioning of the Keck telescope.

**Well worth the trouble**

But all of the work and waiting ultimately paid off, says Tomas Krasuski, the lead electronics engineer at the Keck Observatory: “We can now point the telescopes at any star within Keck’s observable area with an accuracy of one arc second. We were also able to increase performance: not only can we collect data with greater accuracy but we can also process these data faster—and we now have greater dynamic control of the telescope.” The latter point is particularly important when researchers want to observe celestial objects over an extended period, requiring them to continually reposition the telescope. The newly installed HEIDENHAIN encoders contribute to this accuracy.

**Measurement technology not unlike that of a machine tool**

The position measurement of azimuth and elevation is now performed by ERA 8400 modular angle encoders from HEIDENHAIN. These encoders are so-to-say the big brothers within the ERA family. Their smaller siblings, such as the ERA 4000, perform their service on the rotary tables and swivel heads of numerous machine tools. The graduation lines of the ERA 8400 encoders are spaced along the scale tapes at 40-micrometer intervals and are read by four scanning heads for azimuth readings and two for elevation. In conjunction with the EIB 749 evaluation electronics, the measured values can be interpolated down to a measuring step of 10 nanometers.

This translates into attainable telescope positioning accuracies of four milliarcseconds horizontally and one milliarcsecond vertically. “We can now target, track, and observe an individual star, even within a dense star cluster. That gives us entirely new insights and delivers considerably more data than the previous technology could,” says Thomas Krasuski, taking initial stock after completion of the overhaul. “It’s amazing that we can now move such massive technology like our 10-meter telescopes in measuring steps of just 10 nanometers.”
